Bile Duct Cancer Early Detection, Diagnosis, and Staging

Detection and Diagnosis

Finding cancer early, when it's small and before it has spread, often allows for more treatment options. Some early cancers may have signs and symptoms that can be noticed, but that's not always the case.

- Can Bile Duct Cancer Be Found Early?
- Signs and Symptoms of Bile Duct Cancer
- Tests for Bile Duct Cancer

Stages and Outlook (Prognosis)

After a cancer diagnosis, staging provides important information about the extent of cancer in the body and the likely response to treatment.

Questions to Ask About Bile Duct Cancer

Here are some questions you can ask your cancer care team to help you better understand your bile duct cancer and treatment options.

- Questions to Ask About Bile Duct Cancer

Can Bile Duct Cancer Be Found Early?

Only a small number of bile duct cancers are found before they have spread too far to
be removed by surgery.

The bile ducts are deep inside the body, so small tumors can’t be seen or felt during routine physical exams. There are no blood tests or other tests that can reliably detect bile duct cancers early enough to be useful as screening tests. (Screening is testing for cancer in people without any symptoms.) Because of this, most bile duct cancers are found only after the cancer has grown enough to cause signs or symptoms. The most common symptom is jaundice, a yellowing of the skin and eyes, which is caused by a blocked bile duct.

**Signs and Symptoms of Bile Duct Cancer**
Bile duct cancer does not usually cause signs or symptoms until later in the course of the disease, but sometimes symptoms can appear sooner and lead to an early diagnosis. If the cancer is diagnosed at an early stage, treatment might work better.

When bile duct cancer does cause symptoms, it's usually because a bile duct is blocked. Symptoms tend to depend on whether the cancer is in ducts inside the liver (intrahepatic) or in ducts outside the liver (extrahepatic), and include:

**Jaundice**

Normally, bile is made by the liver and released into the intestine. Jaundice occurs when the liver can’t get rid of bile, which contains a greenish-yellow chemical called **bilirubin**. As a result, bilirubin backs up into the bloodstream and settles in different parts of the body. Jaundice can often be seen as a yellowing of the skin and in the white part of the eyes.

Jaundice is the most common symptom of bile duct cancer, but most of the time, jaundice isn't caused by cancer. It's more often caused by hepatitis (inflammation of the liver) or a gallstone that has traveled to the bile duct. But whenever jaundice occurs, a doctor should be seen right away.

**Itching**

Excess bilirubin in the skin can also cause itching. Most people with bile duct cancer notice itching.

**Light-colored/greasy stools**

Bilirubin contributes to the brown color of bowel movements, so if it doesn’t reach the intestines, the color of a person’s stool might be lighter.

If the cancer blocks the release of bile and pancreatic juices into the intestine, a person might not be able to digest fatty foods. The undigested fat can also cause stools to be unusually pale. They might also be bulky, greasy, and float in the toilet.

**Dark urine**

When bilirubin levels in the blood get high, it can also come out in the urine and turn it
Abdominal (belly) pain

Early bile duct cancers seldom cause pain, but bigger tumors may cause belly pain, especially below the ribs on the right side.

Loss of appetite/weight loss

People with bile duct cancer may not feel hungry and may lose weight without trying to do so.

Fever

Some people with bile duct cancer develop fevers.

Nausea and vomiting

These are not common symptoms of bile duct cancer, but they may occur in people who develop an infection (cholangitis) as a result of bile duct blockage. These symptoms are often seen along with a fever.

Keep in mind: Bile duct cancer is rare. These symptoms are far more likely to be caused by something other than bile duct cancer. For example, people with gallstones have many of these same symptoms. And there are many far more common causes of belly pain than bile duct cancer. Also, hepatitis (an inflamed liver most often caused by infection with a virus) is a much more common cause of jaundice.

Still, if you have any of these problems, it’s important to see a doctor right away so the cause can be found and treated, if needed.

Patel T, Borad MJ. Carcinoma of the biliary tree. In: DeVita VT, Lawrence TS,
Tests for Bile Duct Cancer

Most bile duct cancers aren't found until a person goes to a doctor because they have symptoms.

**Medical history and physical exam**

If there's reason to suspect that you might have bile duct cancer, your doctor will want to take your complete medical history to check for risk factors and to learn more about your symptoms.

A physical exam is done to look for signs of bile duct cancer or other health problems. If bile duct cancer is suspected, the exam will focus mostly on the abdomen (belly) to check for any lumps, tenderness, or build-up of fluid. The skin and the white part of the eyes will be checked for jaundice (a yellowish color).

If symptoms and/or the results of the physical exam suggest you might have bile duct cancer, tests will be done. These could include lab tests, imaging tests, and other procedures.

**Blood tests**

**Tests of liver and gallbladder function**

*Lab tests* might be done to find out how much bilirubin is in your blood. Bilirubin is the chemical that causes jaundice. Problems in the bile ducts, gallbladder, or liver can raise
the blood level of bilirubin.

The doctor may also do tests for albumin, liver enzymes (alkaline phosphatase, AST, ALT, and GGT), and certain other substances in your blood. These may be called liver function tests. They can help diagnose bile duct, gallbladder, or liver disease. If levels of these substances are higher, it might point to blockage of the bile duct, but they can't show if it's due to cancer or some other reason.

**Tumor markers**

Tumor markers are substances made by cancer cells that can sometimes be found in the blood. People with bile duct cancer may have high blood levels of the markers called CEA and CA 19-9. High levels of these markers often mean that cancer is present, but the high levels can also be caused by other types of cancer, or even by problems other than cancer. Also, not all bile duct cancers make these tumor markers, so low or normal levels don't always mean cancer is not present.

Still, these tests can sometimes be useful after a person is diagnosed with bile duct cancer. If the levels of these markers are found to be high, they can be followed over time to help see how well treatment is working.

**Imaging tests**

Imaging tests use x-rays, magnetic fields, or sound waves to create pictures of the inside of your body. Imaging tests can be done for a number of reasons, including:

- To look for suspicious areas that might be cancer
- To help a doctor guide a biopsy needle into a suspicious area to take a sample for testing
- To learn how far cancer has spread
- To help make treatment decisions
- To help find out if treatment is working
- To look for signs of the cancer coming back after treatment

Imaging tests can often show a bile duct blockage. But they often can't show if the blockage is caused by a tumor or a less serious problem like scarring.

People who have (or might have) bile duct cancer may have one or more of these tests:

**Ultrasound**
Ultrasound uses sound waves and their echoes to create images of the inside of the body. A small instrument called a transducer gives off sound waves and picks up the echoes as they bounce off organs inside the body. The echoes are converted by a computer into an image on a screen.

**Abdominal ultrasound:** This is often the first imaging test done in people who have symptoms such as jaundice or pain in the right upper part of their abdomen (belly). This is an easy test to have and it doesn't use radiation. You simply lie on a table while a technician moves the transducer on the skin over your abdomen.

This type of ultrasound can also be used to guide a needle into a suspicious area or lymph node so that cells can be removed (biopsied) and looked at under a microscope. This is called an ultrasonography-guided needle biopsy.

**Endoscopic or laparoscopic ultrasound:** In these techniques, the doctor puts the ultrasound transducer inside your body and closer to the bile duct. This gives more detailed images than a standard ultrasound. The transducer is on the end of a thin, lighted tube that has a camera on it. The tube is either passed through your mouth, down through your stomach, and into the small intestine near the bile ducts (endoscopic ultrasound) or through a small surgical cut in the skin on side of your body (laparoscopic ultrasound).

If there's a tumor, the doctor might be able to see how far it has grown and spread, which can help in planning for surgery. Ultrasound may be able to show if nearby lymph nodes are enlarged, which can be a sign that cancer has reached them. Needle biopsies of suspicious areas might be done.

**Computed tomography (CT) scan**

A CT scan uses x-rays to make detailed cross-sectional images of your body. It can be used to

- Help diagnose bile duct cancer by showing tumors in the area.
- Help stage the cancer (find out how far it has spread). CT scans can show the organs near the bile duct (especially the liver), as well as lymph nodes and distant organs where cancer might have spread to.
- A type of CT known as CT angiography can be used to look at the blood vessels around the bile ducts. This can help determine if surgery is an option.
- Guide a biopsy needle into a suspected tumor. This is called a CT-guided needle biopsy. To do it, you stay on the CT scanning table while the doctor advances a
biopsy needle through your skin and toward the mass. CT scans are repeated until the needle is inside the mass. A small amount of tissue (a sample) is then taken out through the needle.

**Magnetic resonance imaging (MRI) scan**

Like CT scans, MRI scans show detailed images of soft tissues in the body. But MRI scans use radio waves and strong magnets instead of x-rays. A contrast material called gadolinium may be injected into a vein before the scan to see details better.

MRI scans can provide a great deal of detail and be very helpful in looking at the bile ducts and other organs. Sometimes they can help tell a benign (non-cancer) tumor from one that's cancer. Special types of MRI scans may also be used in people who may have bile duct cancer:

- **MR cholangiopancreatography (MRCP)** can be used to look at the bile ducts and is described below in the section on cholangiography.
- **MR angiography (MRA)** looks at blood vessels and is also covered in the section on angiography.

**Cholangiography**

A cholangiogram is an imaging test that looks at the bile ducts to see if they're blocked, narrowed, or dilated (widened). This can help show if someone might have a tumor that's blocking a duct. It can also be used to help plan surgery. There are several types of cholangiograms, each of which has different pros and cons.

**Magnetic resonance cholangiopancreatography (MRCP):** This is a way to get images of the bile ducts with the same type of machine used for standard MRIs. Neither an endoscope or an IV contrast agent is used, unlike the other types of cholangiograms. Because it's non-invasive (nothing is put in your body), doctors often use MRCP if they just need images of the bile ducts. This test can't be used to get biopsy samples of tumors or to place stents (small tubes) in the ducts to keep them open.

**Endoscopic retrograde cholangiopancreatography (ERCP):** In this procedure, a doctor passes a long, flexible tube (endoscope) down your throat, through your stomach, and into the first part of the small intestine. This is usually done while you are sedated (given medicine to make you sleepy). A small catheter (tube) is passed out of the end of the endoscope and into the common bile duct. A small amount of contrast dye is injected through the catheter. The dye helps outline the bile ducts and pancreatic
duct as x-rays are taken. The images can show narrowing or blockage of these ducts. This test is more invasive than MRCP, but it has the advantage of allowing the doctor to take samples of cells or fluid for testing. ERCP can also be used to put a stent (a small tube) into a duct to help keep it open.

Percutaneous transhepatic cholangiography (PTC): To do this procedure, the doctor puts a thin, hollow needle through the skin of your belly and into a bile duct inside your liver. You're given medicines through an IV line to make you sleepy before this test. A local anesthetic is also used to numb the area before putting in the needle. A contrast dye is then injected through the needle, and x-rays are taken as it passes through the bile ducts. Like ERCP, this test can also be used to take samples of fluid or tissues or to put a stent (small tube) in the bile duct to help keep it open. Because it's more invasive, PTC is not usually used unless ERCP has already been tried or can’t be done for some reason.

Angiography

Angiography or an angiogram is an x-ray test for looking at blood vessels in and around the liver and bile ducts. A thin plastic tube called a catheter is threaded into an artery and a small amount of contrast dye is injected to outline blood vessels. Then x-rays are taken. The images show if blood flow in is blocked anywhere or affected by a tumor, as well as any abnormal blood vessels in the area. The test can also show if a bile duct cancer has grown through the walls of blood vessels. This information is mainly used to help surgeons decide whether a cancer can be removed and to help plan the operation.

Angiography can also be done with a CT scan (CT angiography) or an MRI (MR angiography). These tend to be used more often because they give information about the blood vessels without the need for a catheter. You may still need an IV line so that a contrast dye can be injected into your bloodstream during the imaging.

Other tests

Doctors may also use special instruments (endoscopes) to go into the body to get a more direct look at the bile duct and nearby areas. The scopes may be passed through small surgical incisions (cuts) or through natural body openings like the mouth.

Laparoscopy

Laparoscopy is a type of surgery. The doctor puts a thin tube with a light and a small video camera on the end (a laparoscope) through a small incision (cut) in the front of
your belly to look at the bile ducts, gallbladder, liver, and other nearby organs and tissues. (Sometimes more than one cut is made.) This is typically done in the operating room while drugs are used to put you into a deep sleep and not feel pain (general anesthesia) during the surgery.

Laparoscopy can help doctors plan surgery or other treatments, and can help determine the stage (extent) of the cancer. If needed, doctors can also use special instruments put in through the incisions to take out biopsy samples for testing. Laparoscopy is often done before surgery to remove the cancer, to help make sure the tumor can be removed completely.

**Cholangioscopy**

This procedure can be done during an ERCP (see above). The doctor passes a very thin fiber-optic tube with a tiny camera on the end down through the larger tube used for the ERCP. From there it can be maneuvered into the bile ducts. This lets the doctor see any blockages, stones, or tumors and even biopsy them.

**Biopsy**

Imaging tests might suggest that a bile duct cancer is present, but in many cases samples of bile duct cells or tissue is removed (biopsied) and looked at with a microscope to be sure of the diagnosis.

But a biopsy isn't always be done before surgery for a possible bile duct cancer. If imaging tests show a tumor in the bile duct, the doctor may decide to proceed directly to surgery and to treat the tumor as a bile duct cancer (see Surgery for Bile Duct Cancer).

**Types of biopsies**

There are many ways to take biopsy samples to diagnose bile duct cancer.

**During cholangiography:** If ERCP or PTC is being done, a sample of bile may be collected during the procedure to look for cancer cells in the fluid. Bile duct cells and tiny pieces of bile duct tissue can also be taken out by biliary brushing. Instead of injecting contrast dye and taking x-ray pictures (as for ERCP or PTC), the doctor advances a small brush with a long, flexible handle through the endoscope or needle. The end of the brush is used to scrape cells and small tissue fragments from the lining of the bile duct. These are then looked at with a microscope.
During cholangioscopy: Biopsy specimens can also be taken during cholangioscopy. This test lets the doctor see the inside surface of the bile duct and take samples of suspicious areas.

Needle biopsy: For this test, a thin, hollow needle is put through the skin and into the tumor without making a cut in the skin. (The skin is numbed first with a local anesthetic.) The needle is usually guided into place using ultrasound or CT scans. When the images show that the needle is in the tumor, cells and/or fluid are drawn into the needle and sent to the lab to be tested.

In most cases, this is done as a fine needle aspiration (FNA) biopsy, which uses a very thin needle attached to a syringe to suck out (aspirate) a sample of cells. Sometimes, the FNA doesn’t get enough cells for a definite diagnosis, so a core needle biopsy, which uses a slightly larger needle to get a bigger sample, may be done.

For more on biopsies and how samples are tested, see Testing Biopsy and Cytology Specimens for Cancer.

Bile Duct Cancer Stages

The stage of a cancer describes how much cancer is in the body. It helps determine how serious the cancer is and how best to treat it. Doctors also use a cancer's stage when talking about survival statistics.

The stage of a bile duct cancer is determined by the results of the physical exam, imaging and other tests, and by the results of surgery if it has been done.

The American Joint Committee on Cancer (AJCC) TNM system

A staging system is a standard way for the cancer care team to sum up the extent of a cancer. The main system used to describe the stages of bile duct cancer is the American Joint Committee on Cancer (AJCC) TNM system. There are actually 3 different staging systems for bile duct cancers, depending on where they start:

- **Intrahepatic bile duct cancers** (those starting within the liver)
- **Perihilar (hilar) bile duct cancers** (those starting in the hilum, the area just outside the liver)
- **Distal bile duct cancers** (those starting farther down the bile duct system)
Nearly all bile duct cancers start in the innermost layer of the wall of the bile duct, called the **mucosa**. Over time they can grow through the wall toward the outside of the bile duct. If a tumor grows through the bile duct wall, it can invade (grow into) nearby blood vessels, organs, and other structures. It might also grow into nearby lymphatic or blood vessels, and from there spread to nearby lymph nodes or to other parts of the body.

**Resectable versus unresectable**

The TNM staging system provides a detailed summary of how far the bile duct cancer has spread and gives doctors an idea about a person’s prognosis (outlook). But for treatment purposes, doctors often use a simpler system based on whether or not the cancer can probably be removed (resected) with surgery:

- **Resectable** cancers are those that doctors believe can be removed completely by surgery.
- **Unresectable** cancers have spread too far or are in too difficult a place to be removed entirely by surgery.

In general terms, most stage 0, I, and II cancers and possibly some stage III cancers are resectable, while most stage III and IV tumors are unresectable. But this depends on other factors, too, such as the size and location of the cancer and whether a person is healthy enough for surgery.

Last Medical Review: July 3, 2018 Last Revised: July 3, 2018

American Cancer Society medical information is copyrighted material. For reprint requests, please see our Content Usage Policy.

**Staging of Intrahepatic Bile Duct Cancers**

After a person is diagnosed with intrahepatic bile duct cancer, doctors will try to figure out if it has spread, and if so, how far. This process is called staging. The stage of a cancer describes how much cancer is in the body. It helps determine how serious the cancer is and how best to treat it. Doctors also use a cancer's stage when talking about survival statistics.

The earliest stage intrahepatic bile duct cancers are stage 0 (also called carcinoma in situ, or CIS). Stages then range from stages I (1) through IV (4). As a rule, the lower the number, the less the cancer has spread. A higher number, such as stage IV, means cancer has spread more. And within a stage, an earlier letter means a lower stage.

Although each person’s cancer experience is unique, cancers with similar stages tend to have a similar outlook and are often treated in much the same way.
How is the stage determined?

The staging system most often used for intrahepatic bile duct cancer is the American Joint Committee on Cancer (AJCC) TNM system, which is based on 3 key pieces of information:

- The extent (size) of the main tumor (T): How large has the cancer grown? Has the cancer reached nearby structures or organs?
- The spread to nearby lymph nodes (N): Has the cancer spread to nearby lymph nodes?
- The spread (metastasis) to distant sites (M): Has the cancer spread to distant lymph nodes or distant organs such as the bones, lungs, or peritoneum (the lining of the abdomen [belly])?

The system described below is the most recent AJCC system, effective January 2018. It's used only for intrahepatic bile duct cancers (those starting within the liver). Staging systems for cancers starting in other parts of the bile ducts are described in:

- Perihilar Bile Duct Cancer Stages (for cancers starting in the hilum, just outside the liver)
- Distal Bile Duct Cancer Stages (for cancers starting farther down the bile duct)

Numbers or letters after T, N, and M provide more details about each of these factors. Higher numbers mean the cancer is more advanced.

Once a person’s T, N, and M categories have been determined, this information is combined in a process called stage grouping to assign an overall stage. For more on this, see Cancer Staging.

Intrahepatic bile duct cancer is typically given a clinical stage based on the results of a physical exam, biopsy, and imaging tests (described in Tests for Bile Duct Cancer). If surgery is done, the pathologic stage (also called the surgical stage) is determined by examining the tissue removed during the operation.

Cancer staging can be complex, so ask your doctor to explain it to you in a way you understand.

Staging of Perihilar Bile Duct Cancers

After a person is diagnosed with perihilar (hilar) bile duct cancer, doctors will try to figure out if it has spread, and if so, how far. This process is called staging. The stage of a cancer describes how much cancer is in the body. It helps determine how serious the cancer is and how best to treat it. Doctors also use a cancer's stage when talking about survival statistics.

The earliest stage perihilar bile duct cancers are stage 0, also called carcinoma in situ (CIS) or high-grade biliary intraepithelial neoplasia. Stages then range from stages I (1) through IV (4). As a rule, the lower the number, the less the cancer has spread. A higher number, such as stage IV, means cancer has spread more. And within a stage, an earlier letter means a lower stage.

Although each person’s cancer experience is unique, cancers with similar stages tend to have a similar outlook and are often treated in much the same way.

How is the stage determined?

The staging system most often used for perihilar bile duct cancer is the American Joint Committee on Cancer (AJCC) TNM system, which is based on 3 key pieces of information:

- The extent (size) of the main tumor (T): Has the cancer grown through the bile duct
or reached nearby structures or organs?

- The spread to nearby lymph nodes (N): Has the cancer spread to nearby lymph nodes?
- The spread (metastasis) to distant sites (M): Has the cancer spread to distant lymph nodes or distant organs such as the bones, lungs, or peritoneum (the lining of the abdomen [belly])?

The system described below is the most recent AJCC system, effective January 2018. It’s used only for perihilar bile duct cancers (those starting in the hilum, just outside the liver). Staging systems for cancers starting in other parts of the bile ducts are described in:

- Intrahepatic Bile Duct Cancer Stages (for cancers starting in bile ducts within the liver)
- Distal Bile Duct Cancer Stages (for cancers starting farther down the bile duct)

Numbers or letters after T, N, and M provide more details about each of these factors. Higher numbers mean the cancer is more advanced.

Once a person’s T, N, and M categories have been determined, this information is combined in a process called stage grouping to assign an overall stage. For more on this, see Cancer Staging.

Perihilar bile duct cancer is typically given a clinical stage based on the results of a physical exam, biopsy, and imaging tests (described in Tests for Bile Duct Cancer). If surgery is done, the pathologic stage (also called the surgical stage) is determined by examining the tissue removed during the operation.

Cancer staging can be complex, so ask your doctor to explain it to you in a way you understand.

Staging of Distal Bile Duct Cancers

After a person is diagnosed with distal bile duct cancer, doctors will try to figure out if it has spread, and if so, how far. This process is called staging. The stage of a cancer describes how much cancer is in the body. It helps determine how serious the cancer is and how best to treat it. Doctors also use a cancer's stage when talking about survival statistics.

The earliest stage distal bile duct cancers are stage 0, also called carcinoma in situ (CIS) or high-grade biliary intraepithelial neoplasia. Stages then range from stages I (1) through IV (4). As a rule, the lower the number, the less the cancer has spread. A higher number, such as stage IV, means cancer has spread more. And within a stage, an earlier letter means a lower stage.

Although each person’s cancer experience is unique, cancers with similar stages tend to have a similar outlook and are often treated in much the same way.

How is the stage determined?

The staging system most often used for distal bile duct cancer is the American Joint Committee on Cancer (AJCC) TNM system, which is based on 3 key pieces of information:

- The extent (size) of the main tumor (T): Has the cancer grown through the wall of the bile duct? Has the cancer reached nearby structures or organs?
- The spread to nearby lymph nodes (N): Has the cancer spread to nearby lymph nodes?
- The spread (metastasis) to distant sites (M): Has the cancer spread to distant lymph nodes or distant organs such as the bones, lungs, or peritoneum (the lining of the abdomen [belly])?

The system described below is the most recent AJCC system, effective January 2018. It's used only for distal bile duct cancers (those starting below the gallbladder).
Staging systems for cancers starting in other parts of the bile ducts are described in:

- **Intrahepatic Bile Duct Cancer Stages** (for cancers starting in bile ducts within the liver)
- **Perihilar (Hilar) Bile Duct Cancer Stages** (for cancers starting in the hilum, just outside the liver)

Numbers or letters after T, N, and M provide more details about each of these factors. Higher numbers mean the cancer is more advanced.

Once a person’s T, N, and M categories have been determined, this information is combined in a process called **stage grouping** to assign an overall stage. For more on this, see [Cancer Staging](https://www.cancer.gov/cancertopics/pdq/treatment/cancerstaging/healthprofessional).

Distal bile duct cancer is typically given an **clinical stage** based on the results of a physical exam, biopsy, and imaging tests (described in Tests for Bile Duct Cancer). If surgery is done, the **pathologic stage** (also called the **surgical stage**) is determined by examining the tissue removed during the operation.

Cancer staging can be complex, so ask your doctor to explain it to you in a way you understand.

Survival Rates for Bile Duct Cancer

Survival rates are often used by doctors as a standard way of discussing a person’s prognosis (outlook). Some people may want to know the survival statistics for people in similar situations, while others might not find the numbers helpful, or might even not want to know them.

When discussing cancer survival statistics, doctors often use a number called the 5-year survival rate. The 5-year survival rate refers to the percentage of patients who live at least 5 years after their cancer is diagnosed. Of course, some of these people live much longer than 5 years.

Five-year relative survival rates, such as the numbers below, assume that some people will die of other causes and compare the observed survival with that expected for people without the cancer. This is a better way to see the impact of the cancer on survival.

To get 5-year survival rates, doctors have to look at people who were treated at least 5 years ago. Improvements in treatment since then may result in a better outlook for people now being diagnosed with bile duct cancer.

There are some important points to note about the survival rates below:

These statistics come from the National Cancer Institute’s SEER program and are based on people diagnosed with bile duct cancer in the years 2000 to 2006. SEER does not separate these cancers by AJCC stage, but instead puts them into 3 groups: localized, regional, and distant. Localized is like AJCC stage I. Regional includes stages II and III. Distant means the same as stage IV.

SEER also does not separate perihilar bile duct cancers from distal bile duct cancers. Instead, these are grouped together as extrahepatic bile duct cancers.

Intrahepatic bile duct cancer

<table>
<thead>
<tr>
<th>Stage</th>
<th>5-year relative survival</th>
</tr>
</thead>
<tbody>
<tr>
<td>Localized</td>
<td>15%</td>
</tr>
<tr>
<td>Regional</td>
<td>6%</td>
</tr>
</tbody>
</table>
Extrahepatic bile duct cancer

<table>
<thead>
<tr>
<th>Stage</th>
<th>5-year relative survival</th>
</tr>
</thead>
<tbody>
<tr>
<td>Localized</td>
<td>30%</td>
</tr>
<tr>
<td>Regional</td>
<td>24%</td>
</tr>
<tr>
<td>Distant</td>
<td>2%</td>
</tr>
</tbody>
</table>

Survival rates are often based on previous outcomes of large numbers of people who had the disease, but they can’t predict what will happen with any particular person. Many other factors can also affect a person’s outlook, such as their age and overall health, and how well the cancer responds to treatment. Even when taking these other factors into account, survival rates are at best rough estimates. Your doctor can tell you how the numbers above apply to you, as he or she knows your situation best.

Questions to Ask About Bile Duct Cancer

It’s important to have honest, open discussions with your cancer care team. They want to answer all of your questions, no matter how minor they might seem. Don’t be afraid to ask them. Here are some questions to get you started:

- Has my cancer spread beyond the bile ducts?
- What is the stage of my cancer, and what does that mean in my case?
- Do I need other tests before we consider treatment options?
- Do I need to see any other kinds of doctors?
- How much experience do you have treating this type of cancer?
- Should I get a second opinion?
- What are my treatment options?
- Can my cancer be removed with surgery?
- What do you recommend and why?
- What is the goal of treatment?
- What risks or side effects are there to the treatments you suggest? How long are they likely to last?
- How quickly do we need to decide on treatment?
- What should I do to be ready for treatment?
- How long will treatment last? What will it be like? Where will it be done?
- How will treatment affect my daily activities?
- What are the chances my cancer can be cured with these treatment plans?
- What would my options be if the treatment doesn’t work or if the cancer comes back?
- What type of follow-up might I need after treatment?
- Where can I get more information and support?

Along with these sample questions, be sure to write down some of your own. For instance, you might want more information about recovery times so you can plan your work or activity schedule. Or you might want to ask about qualifying for clinical trials.
Keep in mind that doctors are not the only ones who can give you information. Other health care professionals, such as nurses and social workers, may have the answers to some of your questions. You can find out more about speaking with your health care team in The Doctor-Patient Relationship.
