About Non-Hodgkin Lymphoma in Children

Overview and Types

If your child has just been diagnosed with non-Hodgkin lymphoma or you are worried about it, you likely have a lot of questions. Learning some basics is a good place to start.

- What Is Non-Hodgkin Lymphoma in Children?
- Types of Non-Hodgkin Lymphoma in Children

Research and Statistics

See the latest estimates for new cases of childhood non-Hodgkin lymphoma in the US and what research is currently being done.

- Key Statistics for Non-Hodgkin Lymphoma in Children

What Is Non-Hodgkin Lymphoma in Children?

Cancer starts when cells in the body begin to grow out of control. Cells in nearly any
part of the body can become cancer, and can then spread to other areas of the body. To learn more about cancer and how it starts and spreads, see What Is Cancer?\textsuperscript{1}

The types of cancers that develop in children are often different from the types that develop in adults. To learn more, see What Are the Differences Between Cancers in Adults and Children?\textsuperscript{2}

Lymphoma is a type of cancer that starts in cells called lymphocytes, which are part of the body’s immune system.

**Hodgkin and non-Hodgkin lymphoma**

The main kinds of lymphomas are:

- **Hodgkin lymphoma (HL)**, also known as Hodgkin disease, which is named after Dr. Thomas Hodgkin, who first described it
- **Non-Hodgkin lymphoma (NHL)**

These lymphomas differ in how they behave, spread, and respond to treatment, so knowing which type your child has is important.

Both of these types are more common in adults, but they can also develop in children and teens. Younger children are more likely to have NHL, while Hodgkin lymphoma is more likely to affect older children and teens.

Different types of NHL can develop in children and teens. Treatment depends on which type of NHL it is, so determining the exact type a child or teen has is important.

Hodgkin lymphoma is treated similarly in children and adults. For more information on this disease, see Hodgkin Lymphoma\textsuperscript{3}.

**The lymph (lymphatic) system**

The cells in which lymphoma starts (lymphocytes) can be found throughout the body’s lymph system, so knowing about the lymph system can be helpful in understanding lymphoma.

The lymph system is part of the body’s immune system, which helps fight infections and some other diseases. It also helps fluids move around in the body.
Lymphocytes

The lymph system is made up mainly of lymphocytes, a type of white blood cell. The main types of lymphocytes are:

- **B lymphocytes (B cells):** B cells normally help protect the body against germs (bacteria or viruses) by making proteins called **antibodies.** The antibodies attach to the germs, marking them for destruction by other parts of the immune system.

- **T lymphocytes (T cells):** There are several types of T cells, each with a special job. Some T cells destroy germs or abnormal cells in the body. Some T cells help boost or slow the activity of other immune system cells.

Lymphomas can develop from either B cells or T cells.

Parts of the lymph system

The lymph system is in many parts of the body, so lymphomas can start almost anywhere. (This can affect what symptoms a child has.)

Lymph tissue is found in:

**Lymph nodes:** Lymph nodes are bean-sized collections of lymphocytes and other immune cells throughout the body. They can sometimes be felt under the skin in the neck, under the arms, and in the groin. Lymph nodes are connected to each other by a system of lymphatic vessels.

Lymph nodes get bigger when they fight infection. Lymph nodes that grow because of infection are called **reactive nodes** or **hyperplastic nodes** and are often painful when they are touched. An enlarged lymph node in a child or teen is most often a reactive node. For example, lymph nodes in the neck are often enlarged in children with sore throats or colds. But a large lymph node is also the most common sign of lymphoma. This is covered in more detail in *Signs and Symptoms of Non-Hodgkin Lymphoma in Children*.

**Spleen:** The spleen is an organ behind the lower ribs on the left side of the body. The spleen makes lymphocytes and other immune system cells. It also stores healthy blood cells and filters out damaged blood cells, bacteria, and cell waste.

**Bone marrow:** The bone marrow is the spongy tissue inside certain bones, which is where new blood cells (including some lymphocytes) are made.
Thymus: The thymus is a small organ behind the upper part of the breast bone and in front of the heart. It’s important in the development of T lymphocytes.

Adenoids and tonsils: These are collections of lymph tissue in the back of the throat. They help make antibodies against germs that are breathed in or swallowed. They are easy to see when they become enlarged during an infection, which occurs often in children.

Digestive tract: Lymph tissue is also scattered throughout the stomach and intestines, and is in many other organs as well.

Types of Non-Hodgkin Lymphoma in Children

There are many types of non-Hodgkin lymphoma (NHL). These cancers are most often classified based on:

- The type of lymphocyte they start in
- How the lymphoma cells look under a microscope
- Whether the lymphoma cells have certain chromosome, gene, or protein changes

Special lab tests are often needed to accurately classify lymphomas. These are described in Tests for Non-Hodgkin Lymphoma in Children.

The most common types of NHL in children and teens are largely different from those in adults. Nearly all childhood NHLs are one of these types:

- Lymphoblastic lymphoma (LBL)
- Burkitt lymphoma (small non-cleaved cell lymphoma)
- Diffuse large B-cell lymphoma (DLBCL)
- Anaplastic large cell lymphoma (ALCL)

All of these types of NHL are considered high-grade or aggressive lymphomas (meaning they tend to grow quickly). Still, it’s important to find out which type a child has because they can be treated differently.

There are many other types of NHL as well. These are much more common in adults and are rare in children, so they are not covered further here.

Lymphoblastic lymphoma

Lymphoblastic lymphoma (LBL) accounts for about 20% of NHL in children and teens in the United States. Boys are about twice as likely to get LBL as girls.

The cancer cells of LBL are very young lymphocytes called lymphoblasts. They are the same cells as those seen in acute lymphoblastic leukemia (ALL) in children. In fact, if more than 25% of the bone marrow is made up of lymphoblasts, the disease is classified and treated as ALL instead of lymphoma.
Most cases of LBL develop from T cells and are called precursor T-lymphoblastic lymphomas. These lymphomas often start in the thymus, forming a mass in the area behind the breast bone and in front of the trachea (windpipe). This can cause problems breathing, which may be the first symptom of LBL.

Less often, LBL develops in the tonsils, lymph nodes of the neck, or other lymph nodes. It can spread very quickly to the bone marrow, other lymph nodes, the surface of the brain, and/or the membranes that surround the lungs and heart.

A smaller fraction of LBLs develop from B cells, and are called precursor B-lymphoblastic lymphomas. These lymphomas more often begin in lymph nodes outside the chest, particularly in the neck. They can also involve the skin and bones.

LBL can grow very quickly and can often cause trouble breathing, so it needs to be diagnosed and treated quickly.

**Burkitt lymphoma**

Burkitt lymphoma, also known as small non-cleaved cell lymphoma, accounts for about 40% of childhood NHL in the United States. It is most often seen in boys, usually between the ages of 5 and 14 years old.

Burkitt lymphoma is named after the doctor who first described it in African children. In certain parts of Africa, Burkitt lymphoma accounts for nearly all childhood NHL and over half of all childhood cancers. In African children this lymphoma usually develops in the jaw or other facial bones.

Burkitt lymphomas in other parts of the world, including the United States, most often start in the abdomen (belly). Typically, a child will develop a large tumor in his or her abdomen that can sometimes block the bowels (intestines). This can cause belly pain, nausea, and vomiting. Burkitt lymphoma can also sometimes start in the neck or tonsils, or rarely in other parts of the body.

This lymphoma develops from mature forms of B lymphocytes (B cells). It can spread quickly to other organs, including the surface of the brain or inside the brain. It is one of the fastest growing cancers known, so it needs to be diagnosed and treated quickly.

A similar type of lymphoma, sometimes called Burkitt-like lymphoma or non-Burkitt lymphoma, also shares some features with diffuse large B-cell lymphoma (described below) when seen under the microscope.
Diffuse large B-cell lymphoma (DLBCL)

This type of lymphoma accounts for about 15% to 20% of childhood NHL. It starts in mature forms of B cells, and it can grow almost anywhere in the body. DLBCL tends to occur more often in older children and teens than among younger children.

Compared to the lymphomas above, DLBCL isn’t as likely to grow as quickly, and it’s less likely to spread to the bone marrow or to the brain or spinal cord. Still, it needs to be treated aggressively, typically the same way that Burkitt lymphoma is treated.

A related but less common type of NHL, known as primary mediastinal B-cell lymphoma (PMBCL), grows as a large mass in the mediastinum (the space between the lungs). It tends to be seen most often in older teens.

Anaplastic large cell lymphoma (ALCL)

This type of lymphoma makes up about 10% of all NHL in children and teens. It usually develops from mature T cells. It may start in lymph nodes in the neck or other areas, and it may be found in the skin, lungs, bone, digestive tract, or other organs.

ALCL tends to develop more often in older children and teens than in younger children. It isn’t as likely to spread to the bone marrow or brain as some other childhood lymphomas, nor does it tend to grow as quickly.

In most children with ALCL, the lymphoma cells have changes in the ALK gene that help the cells grow. Newer targeted drugs called ALK inhibitors, which attack cells with ALK gene changes, have shown promise in treating childhood ALCL in recent years.

Key Statistics for Non-Hodgkin Lymphoma in Children

About 7% of all childhood cancers are non-Hodgkin lymphomas (NHLs).

About 800 children and teens are diagnosed with NHL in the United States each year.

NHL is about 2 to 3 times more common in boys than in girls, and it is more common in White children than Black children.

Overall, the risk of NHL in children increases with age. It can develop in children at any age, but it's uncommon in children younger than 5.

Statistics on survival can be found in Survival Rates for Childhood Non-Hodgkin Lymphoma.

What’s New in Research into Non-Hodgkin Lymphoma in Children?

Research into the causes, diagnosis, and treatment of childhood non-Hodgkin lymphoma (NHL) is being done at many medical centers, university hospitals, and other institutions around the world.

Genetics

As noted in What Causes Non-Hodgkin Lymphoma in Children? scientists are making progress in understanding how changes in the DNA (genes) inside normal lymphocytes
can cause them to develop into lymphoma cells.

Understanding the gene changes that often occur in lymphoma cells can help explain why these cells grow too quickly, live too long, and don't develop into normal, mature cells. More importantly, this information is being used to develop new treatments for lymphoma.

This progress has also led to very sensitive lab tests for detecting and monitoring this disease during treatment. Tests such as the polymerase chain reaction (PCR) can identify lymphoma cells based on some of these gene changes. This test is useful in determining how completely the lymphoma has been destroyed by treatment, and whether a relapse is likely if no further treatment is given.

**Clinical trials of new treatments**

Most children and teens with NHL are treated at major medical centers, where treatment is often given as part of a clinical trial to get the most up-to-date care. Several important questions are now being studied in clinical trials, such as:

- Can some lymphomas be treated with less intense chemotherapy regimens, which might help children avoid some long-term side effects?
- What is the best length of treatment for each type of NHL?
- Can new chemotherapy drugs and new combinations of drugs improve cure rates?
- Can the safety and effectiveness of stem cell transplants be improved on?
- Can newer, targeted drugs such as monoclonal antibodies be helpful in treating NHL, either alone or added to current treatments to make them better? (See Other Drugs for Non-Hodgkin Lymphoma in Children.)
- Can newer forms of immunotherapy (treatments that boost the immune system), such as CAR T-cell therapy or immune checkpoint inhibitors, be helpful in treating childhood NHL, especially if other treatments are no longer working?
