Causes, Risk Factors, and Prevention

Risk Factors

A risk factor is anything that affects your chance of getting a disease such as cancer. Learn more about the risk factors for pancreatic cancer.

- Pancreatic Cancer Risk Factors
- What Causes Pancreatic Cancer?

Prevention

There is no way to prevent all pancreatic cancers. But there are things you can do that might lower your risk. Learn more.

- Can Pancreatic Cancer Be Prevented?

Pancreatic Cancer Risk Factors

A risk factor is anything that affects your chance of getting a disease such as cancer. Different cancers have different risk factors. Some risk factors, like smoking, can be changed. Others, like a person’s age or family history, can’t be changed.

But having a risk factor, or even many risk factors, does not mean that you will get the disease. And many people who get the disease may have few or no known risk factors.

Several factors can affect a person’s chance of getting cancer of the pancreas. Most of these are risk factors for exocrine pancreatic cancer.

Risk factors that can be changed
Tobacco use

Smoking is one of the most important risk factors for pancreatic cancer. The risk of getting pancreatic cancer is about twice as high among smokers compared to those who have never smoked. About 20% to 30% of pancreatic cancers are thought to be caused by cigarette smoking. Cigar and pipe smoking also increase risk, as does the use of smokeless tobacco products.

Overweight and obesity

Being overweight is a risk factor for pancreatic cancer. Very overweight (obese) people are about 20% more likely to develop pancreatic cancer.

Carrying extra weight around the waistline may be a risk factor even in people who are not very overweight.

Workplace exposure to certain chemicals

Heavy exposure at work to certain chemicals used in the dry cleaning and metal working industries may raise a person’s risk of pancreatic cancer.

Risk factors that can’t be changed

Age

The risk of developing pancreatic cancer goes up as people age. Almost all patients are older than 45. About two-thirds are at least 65 years old. The average age at the time of diagnosis is 71.

Gender

Men are slightly more likely to develop pancreatic cancer than women. This may be due, at least in part, to higher tobacco use in men, which raises pancreatic cancer risk (see above). The difference in pancreatic cancer risk was larger in the past (when tobacco use was much more common among men than women), but the gap has closed in recent years.

Race
African Americans are slightly more likely to develop pancreatic cancer than whites. The reasons for this aren’t clear, but it may be due in part to having higher rates of some other risk factors for pancreatic cancer, such as diabetes, smoking in men, and being overweight in women.

Family history

Pancreatic cancer seems to run in some families. In some of these families, the high risk is due to an inherited syndrome (explained below). In other families, the gene causing the increased risk is not known. Although family history is a risk factor, most people who get pancreatic cancer do not have a family history of it.

Inherited genetic syndromes

Inherited gene changes (mutations) can be passed from parent to child. These gene changes may cause as many as 10% of pancreatic cancers. Sometimes these changes result in syndromes that include increased risks of other cancers (or other health problems). Examples of genetic syndromes that can cause exocrine pancreatic cancer include:

- **Hereditary breast and ovarian cancer syndrome**, caused by mutations in the **BRCA1** or **BRCA2** genes
- **Familial atypical multiple mole melanoma (FAMMM) syndrome**, caused by mutations in the **p16/CDKN2A** gene
- **Familial pancreatitis**, usually caused by mutations in the **PRSS1** gene
- **Lynch syndrome**, also known as **hereditary non-polyposis colorectal cancer** (HNPCC), most often caused by a defect in the **MLH1** or **MSH2** genes.
- **Peutz-Jeghers syndrome**, caused by defects in the **STK11** gene. This syndrome is also linked with polyps in the digestive tract and several other cancers.
- **Von Hippel-Lindau syndrome**, caused by mutations in the **VHL** gene. It can lead to an increased risk of pancreatic cancer and carcinoma of the ampulla of Vater.

Pancreatic neuroendocrine tumors and cancers can also be caused by genetic syndromes, such as:

- **Neurofibromatosis, type 1**, which is caused by mutations in the **NF1** gene. This syndrome leads to an increased risk of many tumors, including somatostatinomas.
- **Multiple endocrine neoplasia, type 1 (MEN1)**, caused by mutations in the **MEN1** gene. This syndrome leads to an increased risk of tumors of the parathyroid gland, the pituitary gland, and the islet cells of the pancreas.
Changes in the genes that cause some of these syndromes can be found by genetic testing. For more information on genetic testing, see Can Pancreatic Cancer Be Found Early?

**Diabetes**

Pancreatic cancer is more common in people with diabetes. The reason for this is not known. Most of the risk is found in people with type 2 diabetes. This type of diabetes most often starts in adulthood and is often related to being overweight or obese. It’s not clear if people with type 1 (juvenile) diabetes have a higher risk.

**Chronic pancreatitis**

Chronic pancreatitis, a long-term inflammation of the pancreas, is linked with an increased risk of pancreatic cancer (especially in smokers), but most people with pancreatitis never develop pancreatic cancer.

Chronic pancreatitis is sometimes due to an inherited gene mutation. People with this inherited (familial) form of pancreatitis have a high lifetime risk of pancreatic cancer.

**Cirrhosis of the liver**

Cirrhosis is a scarring of the liver. It develops in people with liver damage from things like hepatitis and heavy alcohol use. People with cirrhosis seem to have an increased risk of pancreatic cancer.

**Stomach problems**

Infection of the stomach with the ulcer-causing bacteria *Helicobacter pylori* (*H. pylori*) may increase the risk of getting pancreatic cancer. Some research has suggested that excess stomach acid might also increase the risk.

**Factors with unclear effect on risk**

**Diet**

Some studies have linked pancreatic cancer to diets that are high in red and processed meats (such as sausage and bacon) and low in fruits and vegetables. But not all studies have found such links, and this is still being studied.
Physical inactivity

Some research has suggested that lack of physical activity might increase pancreatic cancer risk. But not all studies have found this.

Coffee

Some older studies have suggested that drinking coffee might increase the risk of pancreatic cancer, but more recent studies have not confirmed this.

Alcohol

Some studies have shown a link between heavy alcohol use and pancreatic cancer. This link is still not certain, but heavy alcohol use can lead to conditions such as chronic pancreatitis and cirrhosis, which are known to increase pancreatic cancer risk.

What Causes Pancreatic Cancer?

Scientists don’t know exactly what causes most pancreatic cancers, but they have found several risk factors that can make a person more likely to get this disease. Some of these risk factors affect the DNA of cells in the pancreas, which can result in abnormal cell growth and may cause tumors to form.

DNA is the chemical in our cells that carries our genes, which control how our cells function. We look like our parents because they are the source of our DNA. But DNA affects more than just how we look.

Some genes control when our cells grow, divide into new cells, and die:
• Genes that help cells grow, divide, and stay alive are called oncogenes.
• Genes that help keep cell division under control, repair mistakes in DNA, or cause cells to die at the right time are called tumor suppressor genes.

Cancers can be caused by DNA changes (gene mutations) that turn on oncogenes or turn off tumor suppressor genes.

Inherited gene mutations

Some people inherit gene changes from their parents that raise their risk of pancreatic cancer. Sometimes these gene changes are part of syndromes that include increased risks of other health problems as well. These syndromes, which cause a small portion of all pancreatic cancers, are discussed in Risk Factors for Pancreatic Cancer.

Acquired gene mutations

Most gene mutations related to cancers of the pancreas occur after a person is born, rather than having been inherited. These acquired gene mutations sometimes result from exposure to cancer-causing chemicals (like those found in tobacco smoke). But often what causes these changes is not known. Many gene changes are probably just random events that sometimes happen inside a cell, without having an outside cause.

Some of the DNA changes often seen in sporadic (non-inherited) cases of pancreatic cancer are the same as those seen in inherited cases, while others are different. For example, many sporadic cases of exocrine pancreatic cancer have changes in the p16 and TP53 genes, which can also be seen in some genetic syndromes. But many pancreatic cancers also have changes in genes such as KRAS, BRAF, and DPC4 (SMAD4), which are not part of inherited syndromes. Other gene changes can also be found in pancreatic cancers, although often it’s not clear what has caused these changes.

Can Pancreatic Cancer Be Prevented?

There is no sure way to prevent pancreatic cancer. Some risk factors such as age, gender, race, and family history can't be controlled. But there are things you can do that might lower your risk.

Don’t smoke

Smoking is the most important avoidable risk factor for pancreatic cancer. Quitting smoking helps lower risk. If you smoke and want help quitting, please talk to your health care provider or call us at 1-800-227-2345.

Stay at a healthy weight

Getting to and staying at a healthy weight might also help lower your risk. While the effects of getting physical activity and eating well on pancreatic cancer risk are not as clear, both of these can help you stay at a healthy weight.

The American Cancer Society recommends choosing foods and beverages in amounts that help you get to and stay at a healthy weight. Eat a healthy diet, with an emphasis on plant foods. This includes at least 2½ cups of vegetables and fruits every day. Choose whole-grain breads, pastas, and cereals instead of refined grains, and eat fish, poultry, or beans instead of processed meat and red meat. For more, see the American Cancer Society Guidelines on Nutrition and Physical Activity for Cancer Prevention.

Limit alcohol use

Heavy alcohol use has been tied to pancreatic cancer in some studies but not in others. This link is still not certain, but heavy alcohol use can lead to conditions such as chronic pancreatitis and cirrhosis, which are known to increase pancreatic cancer risk.

Limit exposure to certain chemicals in the workplace

Avoiding workplace exposure to certain chemicals may reduce your risk for pancreatic cancer.
