Pancreatic Cancer Causes, Risk Factors, and Prevention

Risk Factors

A risk factor is anything that affects your chance of getting a disease such as cancer. Learn more about the risk factors for pancreatic cancer.

- Pancreatic Cancer Risk Factors
- What Causes Pancreatic Cancer?

Prevention

There is no way to prevent all pancreatic cancers. But there are things you can do that might lower your risk. Learn more.

- Can Pancreatic Cancer Be Prevented?

Pancreatic Cancer Risk Factors

A risk factor is anything that increases your chance of getting a disease such as cancer. Different cancers have different risk factors. Some risk factors, like smoking, can be changed. Others, like a person’s age or family history, can’t be changed.

In some cases, there might be a factor that may decrease your risk of developing
cancer or has an unclear effect. That is not considered a risk factor, but you may see them noted clearly on this page as well.

Having a risk factor, or even many, does not mean that you will get cancer. And some people who get cancer may have few or no known risk factors.

Here are some of the risk factors known to increase your risk for pancreatic cancer.

**Risk factors that can be changed**

**Tobacco use**

*Smoking*¹ is one of the most important risk factors for pancreatic cancer. The risk of getting pancreatic cancer is about twice as high among smokers compared to those who have never smoked. About 25% of pancreatic cancers are thought to be caused by cigarette smoking. Cigar smoking and the use of smokeless tobacco products also increase the risk. However, the risk of pancreatic cancer starts to drop once a person stops smoking. See [Can Pancreatic Cancer Be Prevented?²](#)

**Being overweight**

*Being very overweight (obese)³* is a risk factor for pancreatic cancer. Obese people (body mass index [BMI] of 30 or more) are about 20% more likely to develop pancreatic cancer.

Carrying extra weight around the waistline may be a risk factor even in people who are not very overweight.

**Workplace exposure to certain chemicals**

Heavy exposure at work to certain chemicals used in the dry cleaning and metal working industries may raise a person’s risk of pancreatic cancer.

**Risk factors that can’t be changed**

**Age**

The risk of developing pancreatic cancer goes up as people age. Almost all patients are older than 45. About two-thirds are at least 65 years old. The average age at the time of diagnosis is 70.
Gender

Men are slightly more likely to develop pancreatic cancer than women. This may be due, at least in part, to higher tobacco use in men, which raises pancreatic cancer risk (see above).

Race

African Americans are slightly more likely to develop pancreatic cancer than whites. The reasons for this aren’t clear, but it may be due in part to having higher rates of some other risk factors for pancreatic cancer, such as diabetes, smoking, and being overweight.

Family history

Pancreatic cancer seems to run in some families. In some of these families, the high risk is due to an inherited syndrome (explained below). In other families, the gene causing the increased risk is not known. Although family history is a risk factor, most people who get pancreatic cancer do not have a family history of it.

Inherited genetic syndromes

Inherited gene changes (mutations) can be passed from parent to child. These gene changes may cause as many as 10% of pancreatic cancers. Sometimes these changes result in syndromes that include increased risks of other cancers (or other health problems). Examples of genetic syndromes that can cause pancreatic cancer include:

- **Hereditary breast and ovarian cancer syndrome**, caused by mutations in the \textit{BRCA1} or \textit{BRCA2} genes
- **Hereditary breast cancer**, caused by mutations in the \textit{PALB2} gene
- **Familial atypical multiple mole melanoma (FAMMM) syndrome**, caused by mutations in the \textit{p16/CDKN2A} gene and associated with skin and eye melanomas
- **Familial pancreatitis**, usually caused by mutations in the \textit{PRSS1} gene
- **Lynch syndrome**, also known as \textit{hereditary non-polyposis colorectal cancer} (HNPCC), most often caused by a defect in the \textit{MLH1} or \textit{MSH2} genes
- **Peutz-Jeghers syndrome**, caused by defects in the \textit{STK11} gene. This syndrome is also linked with polyps in the digestive tract and several other cancers.

Changes in the genes that cause some of these syndromes can be found by genetic testing. For more information on genetic testing, see Can Pancreatic Cancer Be Found
Early?5

Diabetes

Pancreatic cancer is more common in people with diabetes. The reason for this is not known. Most of the risk is found in people with type 2 diabetes. This type of diabetes most often starts in adulthood and is often related to being overweight or obese. It’s not clear if people with type 1 (juvenile) diabetes have a higher risk.

Chronic pancreatitis

Chronic pancreatitis, a long-term inflammation of the pancreas, is linked with an increased risk of pancreatic cancer (especially in smokers), but most people with pancreatitis never develop pancreatic cancer.

Chronic pancreatitis is sometimes due to an inherited gene mutation6. People with this inherited (familial) form of pancreatitis have a high lifetime risk of pancreatic cancer.

Factors with unclear effect on risk

Diet

Some studies have linked pancreatic cancer to diets7 that are high in red and processed meats (such as sausage and bacon) and low in fruits and vegetables. But not all studies have found such links, and this is still being studied.

Physical inactivity

Some research has suggested that lack of physical activity8 might increase pancreatic cancer risk. But not all studies have found this.

Coffee

Some older studies have suggested that drinking coffee might increase the risk of pancreatic cancer, but more recent studies have not confirmed this.

Alcohol

Some studies have shown a link between heavy alcohol use9 and pancreatic cancer. This link is still not certain, but heavy alcohol use can lead to conditions such as chronic
pancreatitis, which is known to increase pancreatic cancer risk.

**Infections**

Some research suggests that infection of the stomach with the ulcer-causing bacteria *Helicobacter pylori* (H. pylori) or infection with Hepatitis B may increase the risk of getting pancreatic cancer. More studies are needed.

What Causes Pancreatic Cancer?

We don’t know what causes pancreatic cancer. But we do know many of the risk factors for this cancer (see Pancreatic Cancer Risk Factors\(^1\)) and how some of them cause cells to become cancerous.

Some genes control when cells grow, divide into new cells, and die:

- Genes that help cells grow, divide, and stay alive are called oncogenes.
- Genes that help keep cell division under control or cause cells to die at the right time are called tumor suppressor genes.

Cancers can be caused by DNA changes that turn on oncogenes or turn off tumor suppressor genes.

**Inherited gene mutations**

Some people inherit gene changes\(^2\) from their parents that raise their risk of pancreatic cancer. Sometimes these gene changes are part of syndromes that include increased risks of other health problems as well. These syndromes, which cause a small portion of all pancreatic cancers, are discussed in Risk Factors for Pancreatic Cancer\(^3\).

**Acquired gene mutations**

Most gene mutations related to cancers of the pancreas occur after a person is born, rather than having been inherited. These acquired gene mutations sometimes result from exposure to cancer-causing chemicals (like those found in tobacco smoke\(^4\)). But often what causes these changes is not known. Many gene changes are probably just random events that sometimes happen inside a cell, without having an outside cause.

Some of the DNA changes often seen in sporadic (non-inherited) cases of pancreatic cancer are the same as those seen in inherited cases, while others are different. For example, many sporadic cases of pancreatic cancer have changes in the \(p16\) and \(TP53\) genes, which can also be seen in some genetic syndromes. But many pancreatic cancers also have changes in genes such as \(KRAS\), \(BRAF\), and \(DPC4\) (\(SMAD4\)), which are not part of inherited syndromes. Other gene changes can also be found in pancreatic cancers, although often it’s not clear what has caused these changes.

Can Pancreatic Cancer Be Prevented?

There is no sure way to prevent pancreatic cancer. Some risk factors such as age, gender, race, and family history can't be controlled. But there are things you can do that
might lower your risk.

**Don’t smoke**

Smoking is the most important avoidable risk factor for pancreatic cancer. Quitting smoking helps lower risk. If you smoke and want help quitting, please talk to your health care provider or call us at 1-800-227-2345.

**Stay at a healthy weight**

Getting to and staying at a healthy weight might also help lower your risk. While the effects of getting physical activity and eating well on pancreatic cancer risk are not as clear, both of these can help you stay at a healthy weight.

The American Cancer Society recommends choosing foods and beverages in amounts that help you get to and stay at a healthy weight. Eat a healthy diet, with an emphasis on plant foods. This includes at least 2½ cups of vegetables and fruits every day. Choose whole-grain breads, pastas, and cereals instead of refined grains, and eat fish, poultry, or beans instead of processed meat and red meat. For more, see the American Cancer Society Guidelines on Nutrition and Physical Activity for Cancer Prevention.

**Limit alcohol use**

Heavy alcohol use has been tied to pancreatic cancer in some studies. This link is still not certain, but heavy alcohol use can also lead to conditions such as chronic pancreatitis, which is known to increase pancreatic cancer risk.

**Limit exposure to certain chemicals in the workplace**

Avoiding workplace exposure to certain chemicals may reduce your risk for pancreatic cancer.
